

Reflection: Which component or interaction has the most 'what could go wrong?' annotations? What does this suggest about where engineering effort should be concentrated? Connect your answer to the quality dimensions introduced in Topic 1.

Ans: The Foundation Model has the most important “what could go wrong?” annotations because it may generate incorrect information or hallucinations. The safety and output-checking component is also important because it may fail to identify harmful requests. This suggests that engineering effort should focus on improving accuracy, reliability, and safety. Accuracy can be improved by evaluating the correctness of responses, reliability by testing the system under different conditions, and safety by checking whether harmful requests are handled appropriately. These improvements help make Claude.ai more trustworthy and effective for users.
